# Outline

FSTs and HFST in LT for LRLs

Language models

Error models

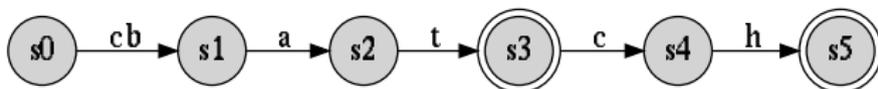

Experiments and Results

# FSTs and Helsinki Finite State Technology

- ▶ simple free open source api for FSTs
- ▶ backed by Uni. Helsinki research projects and researchers
- ▶ lightweight bridging library for various free FST backends—no reinvented wheels or new FST toolkits
- ▶ implements everything needed for legacy interoperability:
  - ▶ Xerox tools (lexc, twolc; xfst under construction)
  - ▶ ispell, aspell, hunspell dictionaries (scripted, under construction)
  - ▶ AT&T/OpenFST tools (=command line interface to finite-state algebra)

## FSTs for language models

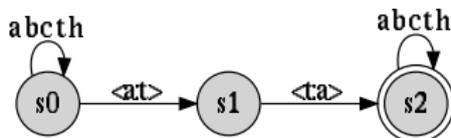

- ▶ common and tested strategy of implementing morphological analyzers in the past
- ▶ expressive enough to be able to encode most (all?) languages' morphological dictionaries
- ▶ theoretically efficient, among the fastest known methods for string matching
- ▶ weights can be used as probabilities of words, morphemes, etc.

A toy language model FSA for {cat,catch,bat,batch}

## FSTs for error models

- ▶ defines translation from misspellings to correct forms
- ▶ can be used for other than spell checking
- ▶ models can be simply combined and extended with FST algebra (=not restricted by tool)
- ▶ weights can be used as probability of errors and their combinations

A toy error model FST for at->ta typo

## Combining language models and error models

- ▶ error model is filter mapping wrong forms to correct ones
- ▶ the erroneous input is transformed to correct variants using composition over error model and language model
- ▶ if both are weighted, weight combining is done by fst algebra

|       |     |     |    |                |
|-------|-----|-----|----|----------------|
| c     | t   | a   | 0  | input          |
| c     | t:a | a:t | 10 | error model    |
| c     | a   | t   | 1  | language model |
| <hr/> |     |     |    |                |
| c     | a   | t   | 11 | result         |

correcting simple typo by composition and tropical (penalty) weighting

# FST language model for spell checking

Any single-tape automaton containing correctly spelled words,  
e.g.:

- ▶ list of correctly written words
- ▶ corpus of word forms with frequencies
- ▶ \*spell dictionaries
- ▶ FST morphologies with Xerox tools

Language models of different sources can be combined using  
FST union

# Handmade models: Xerox tools, \*spell, word-form lists

- ▶ large initial effort: requires lexicon, morphophonology
- ▶ usually maintainable
- ▶ easy to modify for specific purpose, e.g. take subset of correct language for spell checker
- ▶ may be weighted easily by hand, per word-form, per morpheme, etc.

## Semi-automatic models: e.g. Wikipedia collecting

- ▶ `tokenize | sort | uniq -c` to get frequency lists;  
almost no initial effort
- ▶ gets some sort of popular subset of word forms with some  
estimate of correctness
- ▶ e.g. make likelihood of word from frequency  $f_w$  and corpus  
size  $CS$  by simply  $\frac{f_w}{CS}$

# Combination: Training hand-build model with Wikipedia

- ▶ take subset of correctly spelled word forms from Wikipedia and frequencies  $f_w$
- ▶ assign weight to each word according to frequency and corpus size  $CS$  by  $\frac{f_w}{CS}$
- ▶ assign small probability mass to word forms in language model that were not in wikipedia e.g.  $\frac{1}{CS+1}$

# FST error models for suggestion generation

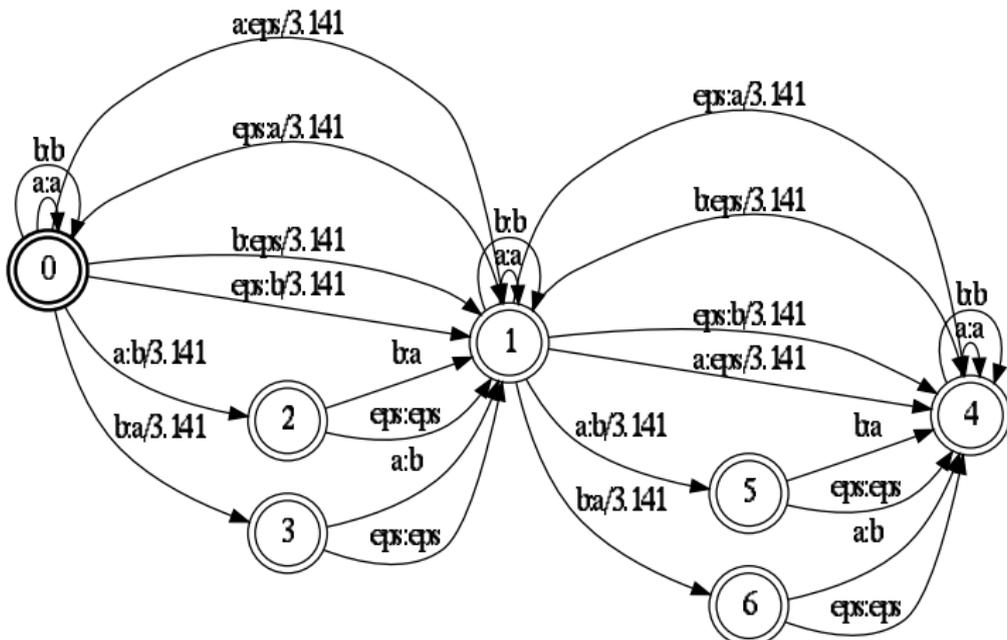

An error model is a two-tape FST mapping misspelt words into correct variants

- ▶ single typing errors, such as edit distance
- ▶ confusion sets for words or character sequences
- ▶ phonetic keying algorithms such as soundex
- ▶ e.g. from hunspell dictionaries: TRY/KEY/REP can be used

## Edit distance models

- ▶ relatively simple model for typos: addition, deletion, substitution or swap of adjacent letters
- ▶ for each alphabet  $a$  draw arcs  $a : 0$ ,  $0 : a$  to end state
- ▶ for each alphabet pair  $a, b$ , draw arc  $a : b$  to auxiliary ending state and afterwards  $b : a$  to end state
- ▶ can be weighted using keyboard layouts, error corpora, rules, ...
- ▶ edit distance without swaps can be built with 1 state, with swaps  $\Sigma^2$  states

# Edit distance 2 for a and b

## Confusion sets over words or character sequences

- ▶ simply modeled by FST paths attached aside other error model with lower or no weight
- ▶ word error like wright:write can be attached to star of the error model as separate path with low weight
- ▶ phonetic error f:ph can be attached by side of edit distance with lower weight

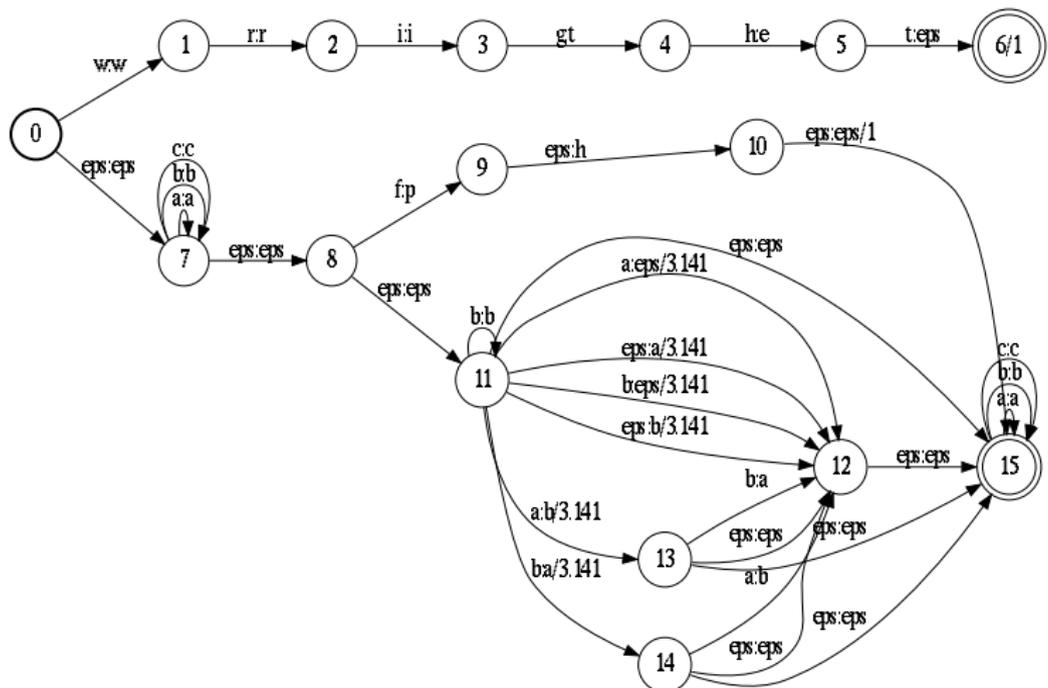

wright->write and f->ph typing errors as FSTs

## Combining FST error models

Since error models were compiled to FSTs we can combine them using finite state algebra, e.g.:

- ▶ correct language model  $S$  is identity mapping of language alphabet without weight
- ▶ edit distance can be combined with other spelling errors and phonetical errors with union e.g.  $ED \cup T_{ph:f}$
- ▶ edit distance of  $N$  is repetition of runs of correct spelling spliced with single edit distance errors:  $ED_N = (SED_1 S)^N$
- ▶ full word misspellings combine with union to make final error model

# Combined error model

## Simple experiments

- ▶ existing free language models: Finnish, Northern Sámi (Xerox tools), English (word list with frequencies)
- ▶ wikipedia frequencies for language model training
- ▶ edit distance 2 with homogenous weights greater than Wikipedia frequency weight
- ▶ existing models were used as is for spell checking
- ▶ trained models were composed with error models for suggestion generation

## Evaluation test setting

- ▶ gold standard of spelling errors hand collected from Wikipedia using original language model (Finnish)
- ▶ other hand made gold standards (English, Northern Sámi)
- ▶ automatically generated errors using simple algorithm generating edit distance errors with probability of  $\sim 0.033$  per character (all languages)

# Evaluation results

| Material   | Rank 1       | 2           | 3           | 4          | Lower        | No rank       | Total          |
|--|--------------|-------------|-------------|------------|--------------|---------------|----------------|
| <b>Wikipedia word form frequencies and edit distance 2</b> |              |             |             |            |              |               |                |
| Finnish  | 451<br>59 %  | 105<br>14 % | 50<br>7 %   | 22<br>3 %  | 62<br>8 %    | 84<br>11 %    | 761<br>100 %   |
